## 1 Introduction

This report specified in detail the design and design criteria for a continuous horizontal hot gas duct (based on report [1]). The design is based on the GTMHR reactor design (helium turbine as heat sink in a one loop plant.) Special data come from Mr. Alan Gerber, FANP SAS (Attachment 1).

The review of the preliminary design for the mechanical design was carried out by EA (Attachment 2). In addition further Finite Element-analyses were carried out by FANP GmbH (Attachment 3)

## 2 Design Conditions

### 2.1 Normal Working Conditions

Normal working conditions are fixed by FANP SAS (see attachment 1). Therefore we have the following data:

Hot gas side:

Helium inlet temperature:
Helium outlet temperature:
Helium pressure:
Helium mass flow:
$850{ }^{\circ} \mathrm{C}$
$848.4^{\circ} \mathrm{C}$
70.8 bar
$316.19 \mathrm{~kg} / \mathrm{s}$
Cold gas side:
Helium inlet temperature:
$487.9^{\circ} \mathrm{C}$
Helium outlet temperature:
$487.8^{\circ} \mathrm{C}$
Helium pressure:
71.6 bar

Helium mass flow:

### 2.2 Transient Working Conditions

Starting with the normal operating conditions, the following transient conditions are defined: ${ }^{1)}$
Hot gas side:

Helium inlet temperature:
Helium outlet temperature:
Helium pressure:
Helium mass flow:
Cold gas side:
Helium inlet temperature:
Helium outlet temperature:
Helium pressure:
Helium mass flow:
starting at $850^{\circ} \mathrm{C} \rightarrow$ ending at $850^{\circ} \mathrm{C}$ in 8.83 s starting at $848,4^{\circ} \mathrm{C} \rightarrow$ ending at $848,4^{\circ} \mathrm{C}$ in 8.83 s starting at $70.8 \mathrm{bar} \rightarrow$ ending at 1.6 bar in 7 s starting at $316.19 \mathrm{~kg} / \mathrm{s} \rightarrow$ ending at $0 \mathrm{~kg} / \mathrm{s}$ in 7 s
starting at $487.9^{\circ} \mathrm{C} \rightarrow$ ending at $284.81^{\circ} \mathrm{C}$ in 8.83 s starting at $487.8^{\circ} \mathrm{C} \rightarrow$ ending at $284.71^{\circ} \mathrm{C}$ in 8.83 s starting at $71.6 \mathrm{bar} \rightarrow$ ending at 1.6 bar in 7 s starting at $318.2 \mathrm{~kg} / \mathrm{s} \rightarrow$ ending at $0 \mathrm{~kg} / \mathrm{s}$ in 7 s
${ }^{1)}$ FANP GmbH has interpreted the transient conditions from attachment 2, chapter 3.3.2, as a turbine rupture and a depressurization of the primary loop. The Ref. 3 from attachment 2 is not available to FANP GmbH.

Handling: restrictive

### 2.3 Geometric Data

Geometric data are set by FANP SAS (see attachment 1). Therefore the following data are used:
Cold gas duct inner diameter:
2,300 mm
Hot gas duct outer diameter:
$1,700 \mathrm{~mm}$
Hot gas duct inner diameter:
$1,450 \mathrm{~mm}$
Hot gas duct wall thickness:
25 mm (support wall thickness)

### 2.4 Material data

Material data are set by FANP SAS (see attachment 1). Therefore the following data are used:
Metal alloy 1.4876 (X10NiCrAITi32-21 or X10NiCrAITi32-20)
This material is used for all metal structure inside the hot gas duct except the support tube.

## Metal alloy 1.4571 (X6CrNiMoTi17-12-2)

This material was chosen primarily for the support tube of the hot gas duct.

## Insulation material

All insulation areas are filled with fibre mats, containing min. $95 \% \mathrm{Al}_{2} \mathrm{O}_{3}$ and approx. $5 \% \mathrm{SiO}_{2}$ ceramic materials. This fibre material is manufactured in mat form and is delivered in pad form.

Handling: restrictive

## 3 Design of the continuous hot gas duct

FANP GmbH produced a draft for a hot gas duct module using the geometric data given above and the mechanical design module common in the nuclear industry.

This design was developed based on the experience FANP GmbH had gained from previous HTRprojects and was characterized by the following points:

- Shop fabrication from assembly modules
- All welds within the module were already tested by X ray or Ultra Sonic method in the factory.
- Only two site welds required between the modules on site.
- Site welds can be tested by Ultra Sound.
- All components are optimized for stress-loading.
- All welds are outside of the high-load areas and can be fully tested.

Further details can be found in attachment 1.

Handling: restrictive

### 3.1 Structural analysis by EA

The report (attachment 2) was checked regarding content on the following points:
a) Input data used ( Geometry, loading, materials)
b) Methods and verification procedures
c) Results and conclusions
d) Variants A, B and C

### 3.1.1 Input data used (Geometry, loading, materials)

With regards to geometry, the essential main dimensions, named in 2.3 were given in the text. On the basis of the reference of the FANP report ZFY116-0600191597 it is assumed that the Finite Element-Model was taken from the structure of the engineering drawing.

The following corrections - basis for a more detailed investigation - are necessary regarding the technological properties used on page 3-1:

- The data on specific heat, Cp , is given in $\mathrm{KJ} / \mathrm{kgK}$ not in $\mathrm{J} / \mathrm{kgK}$.
- The data for E-Module E are given in Pa not in MPa.

On the basis of this necessary information about consistency of units in the FEM calculations, these corrections can matter whereby the specific material heat is not relevant for the static calculations. But these variables definitely matter for the transient analysis on heat transfer.

On the basis of the high stresses included (see page 4-3) it is assumed that the non-linearity in the behavior of the material remains unconsidered. It is therefore also assumed that an elastic behavior was used, since there was no indication that a plastic deformation (strain) was undertaken.

### 3.1.2 Methods and verification procedures

As a reference to the applied standard, only the ASME II Dev. 1-NH is on page 4-3. There are no references to be found on the generally accepted approach of primary and secondary diaphragm and bending stresses. There is a reference to an acceptable secondary stress of $2 \mathrm{Rp}_{0,2}$ on page 4-3. This stress limit has to be investigated in further work. It is also valuable to confirm in the report to what extent time-dependant temperature methods are considered. For the component being tested it is necessary to conduct a verification analysis for expansion with time and temperature dependant limits in accordance with KTA 3221. This means limits of stress and expansion with time and temperature dependant limits under detailed examination of fatigue levels and classification of stress and binding as well as a relax action and creep.

### 3.1.3 Results and conclusions

The conclusions on pages 4-3 to 4-5 (4-7) have need further work, so that the chosen construction for the design input satisfies the requirements of a preliminary optimized design. FANP GmbH has therefore decided to confirm the design using the data available at the present time with its own FEM analysis.

### 3.1.4 Variants A, B and C

In the report attachment 2, the reference solution A is considered according to ZFY1160600191597 of the FANP GmbH with FEM-Analysis and also thermosleeves created by EA in an S-curve-form (type B) or a stair-form (type C) and additional variations.

These EA designs were not included by FANP GmbH in its own considerations for the following reasons:

- Both the type B and the type C include welds which are not acceptable as primary system components in the German nuclear industry.
- None of the chosen welds can be tested for accuracy by an X-ray or an Ultra Sonic-test.
- The installation of individual hot gas duct components as shown in the FANP GmbH drawings is not possible for the selected thermosleeve-forms without a gap in the insulated area.

### 3.1.5 Filter type A and B

In chapter 5.2.1 of appendix 2, it is assumed that ceramic rings are placed between the perforated piping and the flow duct. This assumption leads to unavoidable consequences during depressurization events.

In the design FANP GmbH used round spacers between both metal sheets. A larger flow cross section ensures the outflow of the helium gas that penetrated the insulation from the insulation space in the drainage column and from the draining column in the free flow cross section.

The filter for the pressure relief of the isolated area which is shown in FIGURE E of appendix 2 does not fulfill the following tasks, which are believed to be mandatory:

- Minimization of the pressure difference between the drainage gap and the free flow cross section
- Stress-strain compensation of different stresses between the liner tube and the support pipe due to the tendency for helium friction welding when movement occurs.
- Low flow velocity within the isolated area through pressure relief.
- The design does not comply with German nuclear regulations.

The installation of this device as well as the installation of the hot gas duct component between the L-Shape is not believed to be carried out (see positioning of the welds, support pipe and liner).

Handling: restrictive

## 4 FEM analyses concerning continuous, horizontal hot gas duct

The present design for the hot gas duct, especially the spacres between the inner liner and the support tube, is evaluated for the operational conditions and on Accident Load Case. For the incident and accident conditions conclusions are made.

The evaluation is based on the preliminary KTA 3221.1 and KTA 3221.2. The hot gas duct with operating conditions of $488^{\circ} \mathrm{C}$ at the support tube und $850^{\circ} \mathrm{C}$ at the inner liner is classified for Temperature category III. With respect to the classification the structural analyses include evaluation of primary and secondary strains and stresses and the consideration of elastic-plastic material behaviour together with the assessment of creep behaviour. The threshold values are time-temperature depending values.

The evaluation is done by the FE-Method with the computer code ANSYS 7.1.
Details see Work-Report NGPM5/2003/en/0285 from 30.12.2003 (attachment 3).
With respect to the available information and made estimations it can concluded that the design resist the load for the normal operation (usage factor 0,11 ). Critical items are stress concentration with respect to material and geometrical discontinuities. Welds has to be minimized in principle and not considered here

The investigated design for the hot gas duct seems to resist the defined loadings, but not all load cases were considered and material discontinuities were neglected. Furthermore it should be considered that welds have to be minimized and the geometrical design should preclude any stress concentration. A final statement and design optimization should include further load cases and the check if any further loads from boundary conditions has to be considered (e.g. seismic loads).

Handling: restrictive

## 5 Conclusions

Based on the continuous hot gas duct reference design (attachment 1), thermo mechanical calculations have been carried out for both the normal operating conditions and transients. In particular, the design of the continuous horizontal hot gas duct and the behavior of the thermal insulation were analyzed.

This review took place with the current available data and took into account a normal operation as well as a general plant transient. At a later date additional analyses for loop calculations will have to be carried out.

Taking into account the comments regarding EA as well as the additional analyses performed by FANP, the design is acceptable. The selected design can be retained for further development.

However, FANP GmbH recommends the production of the support pipe out of the 1.4876 material because of planned high cold gas temperatures. As a result unacceptably high temperatures at the support pipe under accident conditions can be avoided and a structural integrity can be assured.

In conclusion the following must be pointed out:
The analyses carried out by FANP GmbH used estimates from earlier HTR-projects. The material data were taken from the KTA-regulations "draft" in Germany.

Up to now no standards (HTR-L) or material data (HTR-M) concerning the functional design for components for a HTR has been specified. Therefore it cannot be ruled out that an upgrading of the chosen design will be necessary due to the application of a binding standard at a later date.

## i |niticoiduchtion

This report describes the design for a continuous horizontal hot gas duct in detail. The design is based on the data from Mr. Alain Gerber from NFEVES (see attachment 1) for the hot gas duct for the GT-MHR reactor design.

The continuous horizontal hot gas duct is split in several sections. Each normal section is 1620 mm long. For connecting to the upper core structure or the helium turbine inlet we need shorter sections, but for the FEM-analyses made by EA the longest section should by calculate.

In the attachments 3 to 5 the detailed construction for the continuous hot gas duct is shown.

Handling: restricted

## 

Normal working conditions are fixed by NFEVES (see attachment 1). Therefore we have the following data:

Hot gas side:
Helium inlet temperature: $\quad 850{ }^{\circ} \mathrm{C}$
Helium outlet temperature: $848,4^{\circ} \mathrm{C}$
Helium pressure: 70,8 bar
Helium mass flow: $316,19 \mathrm{~kg} / \mathrm{s}$

Cold gas side:
Helium inlet temperature: $\quad 487,9^{\circ} \mathrm{C}$
Helium outlet temperature: $\quad 487,8{ }^{\circ} \mathrm{C}$
Helium pressure: 71,6 bar
Helium mass flow:
$318,2 \mathrm{~kg} / \mathrm{s}$

## (3) |VEteltals

The materials chosen are specified in our e-mail dated 13. January 2003 (see attachment 2).
For the fibre insulation you must calculate with a thermal conductivity of $0.55 \mathrm{~W} / \mathrm{mK}$ at the temperature of $850^{\circ} \mathrm{C}$.

## 4! Sgectal Defte

In completion we specified following data:
. Each insulation fibre area is filled with $90 \mathrm{Vol} \%$ helium.
. The shown depressurisation gaps in the positions 1,5 and 6 are only pre designed. This design must be confirmed by the FEM-calculations.
. The shown depressurisation gap between position $5 / 6$ and $7(15 \mathrm{~mm})$ and the ring outlet inside the liner ( 100 mm ) are only pre designed. This design must be confirmed by the FEMcalculations.

VANVOR Dieter NGES3; Laurent BRIOTTET (E-mail); BREUIL Eric NFEVEI;
HAMY Jean Marie NFEVEK
GT-MHR : nominal working conditions

Dear Arturo,
In your E-mail to M. Venvor dated January the 9th about "HTR-E, WP1, Task D7b, Hot gas duct", you ask nominal working conditions data. These are the following (GT-MHR data) :

1 - NOMINAL OPERATING CONDITIONS
Hot gas size :
Helium inlet temperature : $850^{\circ} \mathrm{C}$ ( $=$ core outlet)
Helium outlet temperature : $848,4^{\circ} \mathrm{C}$ (=turbine inlet)
Helium pressure : $7,08 \mathrm{MPa}$
Helium mass flow: $316,19 \mathrm{~kg} / \mathrm{s}$
Cold gas side :
Helium inlet temperature : $487,9^{\circ} \mathrm{C}$ (=recuperator outlet)
Helium outlet temperature : $487,8^{\circ} \mathrm{C}$ (=core inlet)
Helium pressure : $7,16 \mathrm{MPa}$
Helium mass flow: $318,2 \mathrm{~kg} / \mathrm{s}$

## 2 - NORMAL OPERATION, LOAD CYCLING

The reactor load can be decreased from $100 \%$ to $30 \%$ (and inversely) at two load changes levels :

- low load change : 0,6\% per minute
- rapid load change : within the range of $6 \%$ to $10 \%$ per minute.
- At 0,6\% per minute, on both hot and cold gas sides:
* Transient induced temperatures variations are not significant.
* Transient induced pressure variations is about 0.042 MPa per minute
* Transient induced flowrate variations is $1,9 \mathrm{~kg} / \mathrm{s}$ per minute
- We have performed some calculations in the past concerning load change from $100 \%$ to $30 \%$ at $10 \%$ load change level. It can be retained in a conservative approach:
* Outlet core temperature is regulated, so there is no variation of hot gas side temperatures
* Cold gas side temperature variation is -9 K per minute at transient beginning, $+1,14 \mathrm{~K}$ per minute at end.
* For both hot and cold gas sides, transient induced flowrate variation is $-12,23 \mathrm{~kg} / \mathrm{s}$ per minute in transient beginning, then $-1,74 \mathrm{~kg} / \mathrm{s}$ per minute at the end.
- No data available for $30 \%$ to $100 \%$ transient, our fisrt calculations are not correct (code problems). Moreover it depends of Helium Service System capacity to fill the helium inventory. In a first approach, inverse data of transient from $100 \%$ to $30 \%$ should be retained.

## 3- GEOMETRICAL DATA

- Cold gas duct inner diameter : 2300 mm
- Hot gas duct outer diameter: 1700 mm
- Hot gas duct inner diameter : 1450 mm
- Hot gas duct wall thickness : 25 mm

4 - NEXT DATA
As promised in the november meeting in Juelich, we will produce envelope operation data for transient conditions in March 2003.

## Von: VANVOR Dieter NGES3

Gesendet: Montag, 13. Januar 2003 14:44
An: 'abp@empre.es'

Betreffi: AW: HTR-E, WP1, Task D7b, Hot Gas Duct
Dear Arturo Buenaventura,
To your E-Naiai we take position as follows:
Objective and scope of the analysis
We need a FEM analysis of all construction units of the hot gas duct. This meens for detail:

- for the liner and the perforated pipe with a boil pressure of about 10 bars at $900^{\circ} \mathrm{C}$
- for the vee-shiaped spacers for à temperature differenz of about 600 K
- for the support pipe for a boil pressure af about 10 bars at $540^{\circ} \mathrm{C}$

But this data must be spezifide by NFEVEI!
Detailed geometry of the Hot Gas Duct:
This data and design specifications have to be fixed bei NFEVEI !

## Materials:

Metal alloy $\mathbf{1 . 4 8 7 6}$ for the liner, perforated pipe and the hot side of the vee-shaped sacer
Basis for the material parameters are the standards indicated according to German "Stahlischlussel, 2001). In this steel key as basis standard the EN 1009-1 indicates. In Germany also the material sheet SEW 470 is permissible

The material is classified as follows:
1.4876 X10NiCrAITi32-21 / X10NiCrAITT32-20
in USA: Type B 163, UNS No. N 08800 or $N 08810$ (AISI/SAE)
France: AFNOR Z 10 NC 32-21
Spain: UNE F. 3314 -X 10 NiCrAITi 32-20
GB: B.S. NA 15 ( XH )
Japan: JIS NCF 800 (TP)
Metal alloy 1.4571 for the cold side of the vee-shaped spacer an the support pipe
Basis for the material parameters are the standards indicated according to German "Stahlschlüssel, 2001). In this steel key as basis standard the EN 10028-7 and EN 10088-1 one indicates.

The material is classified as follows:
1.4471 X6CrNiMoTi17-12-2
in USA: Type $316 T 1$, UNS No. S 31635 (AISI/SAE)
France: AFNOR Z 6 CNDT 17-12
Spain: UNE F. 3535 - X 6 CrNiMoTi 17122
GB: B.S. 320 S 31
Japan: JIS SUS 316 Ti
The boundary conditions and Nominal working conditions:
This data and design specifications have to be fixed bei NFEVEI!
Best regards

Dear Mr Vanvor,
As discussed during last HTR-E Meeting held in FZJ (Nov. 2002), we will carry out the themo-mechanical analysis of the horizontal Hot Gas Duct between the reactor and the PCU

We are willing to start working as soon as possible, so we request from you the required input data for the analysis:

Objective and scope of the analysis (different types of analysis you require us to perform, results you need, etc..)
Detailed geometry of the Hot Gas Duct (Diameter, etc..)
Materials (if German reference, the equivalence or directly the list of characteristics)
The boundary conditions (fixing of reactor side and PCU side Hot Gas Duct extremities)
Nominal working conditions
We are aiming to have the FE Model and calculations for nominal working conditions by March 2003.

Best regards,
Arturo Buenaventura

## 1. PURPOSE

The purpose of this document is to present the trade off of the HTR hot gas duct.

The studies performed cover the different configurations for spacers between the support tube and the liner. In these studies, some alternatives for the components that serve as a filter during He pressure drop have been considered.

This report is Empresarios Agrupados" contribution to Deliverable 7b, "Thermal insulation of the turbine inlet ${ }^{\text {² }}$ of HTR-E, WP1, "Turbine".

## 2. INTRODUCTION

The hot gas duct is part of the reactor Power Conversion Unit (PCU). It is the component that connects the HTR Module Reactor and the helium turbine.

The purpose of the hot gas duct is to conduct the high temperature helium coming out of the reactor core to the helium turbine and to feed the reactor with helium coming from the PCU Recuperator. It should be isolated in order to minimise thermal losses (improving cycle efficiency) and to limit the maximum material operating temperature.

The hot gas duct reference design proposed by Framatome ANP Refs 1 and 2consists of two coaxial ducts. High temperature helium flows through the inner part of the duct of minimum diameter, from the reactor to the turbine. The feed helium flows through the region limited by both the inner and outer ducts, from the recuperator to the reactor. The helium operating pressure is approximately the same in the "hot-gas side ${ }^{m}$ and the "cold-gas side". Therefore, only the outer duct is part of the pressure boundary.

The advantage of this design is that the duct conducting the high temperature helium is not part of the pressure boundary. As a result, the material of this duct, working at temperatures over $800^{\circ} \mathrm{C}$, will not be subjected to the design pressure and will only be subjected to relatively small pressure differences during transient conditions. The analyses performed and reported in this document only refer to this inner duct of the hot gas duct. The outer duct is outside the scope of this study.

## 3. CALCULATION HYPOTHESES

### 3.1 REFERENCE HOT GAS DUCT

The different analyses have been carried out using a reference hot gas duct with the following geometrical characteristics (Ref. 2):
: Outside diameter of the support tube (cold duct side) $\mathrm{De}=1700 \mathrm{~mm}$

- Inside diameter of the liner (hot duct side) $\mathrm{Di}=1450 \mathrm{~mm}$
D. Thickness of the support tube $\mathrm{Te}=25 \mathrm{~mm}$
- Thickness of the liner $\mathrm{Ti}=10 \mathrm{~mm}$
- $\quad$ Duct material $\boldsymbol{m}$ Alloy 1.4876 or 1.4571

### 3.2 MATERIAL PROPERTIES

### 3.2.1 Metal Parts

The different metal parts of the hot duct are made of alloy 1.4876 or 1.4571 , the properties of which are similar. Table 2-1 below shows their properties at different temperatures (Ref 4):

Table 2-1

| Temp <br> $\left({ }^{\circ} \mathbf{C}\right)$ | $\mathbf{K}$ <br> $(\mathbf{W} / \mathbf{m ~ K})$ | $\boldsymbol{\alpha}$ <br> $(\mathbf{1 / K})$ | $\mathbf{C p}$ <br> $(\mathbf{J} / \mathbf{k g ~ K})$ | $\varphi$ <br> $\mathbf{( k g / \mathbf { m } ^ { 3 } )}$ | $\mathbf{E}$ <br> $\mathbf{( M P a )}$ | $\mathbf{R p}_{0.2}$ <br> $(\mathbf{M P a})$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 200 | 17 | $17 \mathrm{E}-6$ | 0.49 | 7850 | $186 \mathrm{E}+9$ | 150 |
| 400 | 20 | $18 \mathrm{E}-6$ | 0.52 | 7850 | $172 \mathrm{E}+9$ | 125 |
| 600 | 22.5 | $19 \mathrm{E}-6$ | 0.59 | 7850 | $155 \mathrm{E}+9$ | 115 |
| 850 | 26 | $19.5 \mathrm{E}-6$ | 0.63 | 7850 | $120 \mathrm{E}+9$ | 84 |

### 3.2.2 Insulating Material

A Saffil type material has been considered as insulation between the hot and cold duct sides. It is formed of ceramic fibres containing $95 \% \mathrm{Al}_{2} \mathrm{O}_{3}$.

Ref 1 gives the equivalent thermal conductivity values measured for this material with a packing density of $160 \mathrm{~kg} / \mathrm{m}^{3}$ in an He fluid at 40 bar. These values are shown in Table 2-2 below:

Table 2-2

| Temp $\left({ }^{\circ} \mathrm{C}\right)$ | 400 | 600 | 800 | 1000 |
| :--- | :---: | :---: | :---: | :---: |
| $\mathbf{K}(\mathbf{W} / \mathbf{m K})$ | 0.296 | 0.465 | 0.571 | 0.682 |

In accordance with Ref 2, a single equivalent conductivity value of $0.55 \mathrm{~W} / \mathrm{mK}$ is used in the calculations.

The equivalent thermal conductivity value mainly affects the total heat transmitted in the hot duct and includes the material thermal conductivity, the convection and the radiation present during the test.

### 3.3 LOAD CASES CONSIDERED

In accordance with Ref 3, the maximum loads to be considered in the design of the hot duct will be based on the following events:
a $\quad$ Normal operating conditions $\equiv$ Conditions in accordance with section 3.3.1

- Thermal and pressure transient loads Conditions in accordance with section 3.3.2

### 3.3.1 Normal Operating Conditions

The following are the He conditions considered on the "hot-gas" and "cold-gas" sides of the hot gas duct during normal operating conditions (Ref 2):

Hot gas side

- Helium temperature $\Rightarrow 850^{\circ} \mathrm{C}$
- Helium pressure $=70.8 \mathrm{bar}$
- Helium mass flow $=316.19 \mathrm{~kg} / \mathrm{s}$

Cold gas side

- $\quad$ Helium temperature $\equiv 488^{\circ} \mathrm{C}$
- Helium pressure $\mathbf{\text { 玉 }} \mathbf{7 1 . 6}$ bar
- $\quad$ Helium mass flow $\equiv 318.2 \mathrm{~kg} / \mathrm{s}$

### 3.3.2 Thermal and Pressure Transient Loads

According to Ref. 3, the maximum transient loads to be considered are:

- Maximum temperature gradient of cold gas side $\mathrm{He} \boldsymbol{\mathrm { E }} \boldsymbol{\Delta T}=-23^{\circ} \mathrm{C} / \mathrm{s}$ for 8.83 s , starting from the operating conditions
a Maximum pressure gradient of cold gas side $\mathrm{He} \mathrm{E} \mathrm{EP}=1.0 \mathrm{MPa} / \mathrm{s}$ for 7 s , starting from the operating conditions.

## 3.4 <br> PRESSURE DROP IN THERMAL INSULATION

The hot duct pressure drop events will start a process to remove the He stored in the space occupied by the thermal insulation. It must be borne in mind that the thermal insulation occupies less than $10 \%$ of the total volume, so the remaining volume will therefore be occupied by He .

To evaluate the pressure differences between the hot gas side (thermal insulation chamber) and the cold gas side He , the pressure drop which will take place in the thermal insulation during a pressure drop event must be estimated.

This pressure drop is estimated on the basis of Ref 5 which gives the following values for pressure drop in air at 1 bar for each metre length of insulation:

D Compacted fibres $\Rightarrow \Delta \mathrm{P}\left(\mathrm{N} / \mathrm{m}^{2}\right) \approx 680 \mathrm{~V}^{1.097}(\mathrm{~V} \Rightarrow$ Velocity of the air $\mathrm{m} / \mathrm{s})$
$\therefore \quad$ Tissues or wrapped fibres $\equiv \Delta P\left(N / m^{2}\right) \approx 600 V^{1.155}(\mathrm{~V} \equiv \mathrm{~m} / \mathrm{s})$

These pressure drop values have been compared to the pressure drop values provided by the manufacturers of glass fibre materials used in filters and the results were similar to those obtained with the formulae.

These are only approximate values as there will be different factors to take into account, such as the extent to which the insulating material is compacted. In any event, we shall consider these pressure drop values to be multiplied by an increase coefficient of four (4) in order to perform conservative pressure drop calculations.

To extrapolate the values of pressure drop in air to values of pressure drop in He at pressures other than 1 bar and different temperature values, we shall consider a pressure drop value multiplied by the ratio of densities between the He and the air $\left(\approx 1 \mathrm{~kg} / \mathrm{m}^{3}\right.$ ).

### 3.5 He VELOCITY DURING PRESSURE DROP

The hot duct pressure drop events will start a process to remove the He stored in the space occupied by the thermal insulation. The following formula has been used to evaluate the velocity of He discharge during these events:

where:

- Point (1) is the initial state and point (2) is a state during the pressure drop event
= $\quad P_{1,2}$ 를 pressure
- $\quad \mathrm{T}_{1,2}$ 릉 temperature
$0 \quad \mathrm{~d}_{1,2} \equiv$ density
$\therefore \quad \mathrm{K}=1.666(\mathrm{Cp} / \mathrm{Cv}$ of the He$)$

If during the pressure drop event we consider the following calculation data:
$0 \quad$ Variation in pressure over time $\equiv \mathrm{EP}=\frac{\Delta \mathrm{P}}{\boldsymbol{\Delta t}}(\mathrm{Pa} / \mathrm{s})$
$0 \quad$ Flow area in He discharge $=$ As $\left(\mathrm{m}^{2}\right)$
0 Volume of He enclosed in the isolation chamber $\equiv \mathrm{Vo}\left(\mathrm{m}^{3}\right)$
: He discharge flow $\equiv \mathrm{q}_{2}(\mathrm{~kg} / \mathrm{s})$

With these data, the He discharge velocity $\left(\mathrm{V}_{2}\right)$ as it passes through the flow area As is calculated as follows:

## 4. CONNECTING SPACERS BETWEEN SUPPORT TUBE AND LINER

## 4.1 <br> GEOMETRICAL CONFIGURATIONS STUDIED

To connect the support tube structure and the liner, a metal spacer is installed which ensures that:
a The thermal dilations between the external support tube and the liner are compatible, so that the stresses on the connection are as low as possible
a A solid stiff connection is established between the external support tube and the liner

### 4.1.1 $\quad$ Type $A=V$-shaped Spacer (Reference Design)

d $\quad 4 \mathrm{~mm}$-thick metal plate, forming a single V -shape part

- Each of these spacers is machine form forged. The machined part includes part of the support tube and the liner
a The dimensions considered are shown in Figure A of Appendix A

### 4.1.2 $\quad$ Type B-2L-shaped Spacers

- Formed by a 5 mm thick cylindrical plate. This plate is connected to the liner by means of a 10 mm thick perpendicular plate and to the support tube by means of an 8 mm thick perpendicular plate

D The three plates which comprise the spacer are manufactured from cut plates which are welded together
$0 \quad$ The spacer is connected to the liner and the support tube by means of welds

- The dimensions considered are shown in Figure B of Appendix A

### 4.1.3 Type C L LCL-shaped Spacer

- Formed by two 5 mm and 8 mm thick cylindrical plates. These plates are connected to the liner by means of a 10 mm thick perpendicular plate and to the support tube by means of an 5 mm thick perpendicular plate
- The plates which comprise the spacer are manufactured from cut plates which are welded together
a The spacer is connected to the liner and the support tube by means of welds
a The dimensions considered are shown in Figure $C$ of Appendix $A$

## $4.2 \quad$ THERMAL STRESSES ON THE SPACERS

### 4.2.1 Stress States in Normal Operating Conditions

Three types of spacers for a hot duct configuration have been analysed defined by the following:
v Geometry of the support tube and liner in accordance with the data given in section 3.1
a Thermal conductivity of the insulation between the support tube and liner in accordance with section 3.2.2

- Temperature of $488^{\circ} \mathrm{C}$ considered on the external face of the support tube in accordance with section 3.3.1
- Temperature of $850^{\circ} \mathrm{C}$ considered on the internal face of the liner in accordance with section 3.3.1

A finite element model has been built of each of the three types of spacers and thermo-mechanical analyses have been performed to obtain the maximum stress states on the spacers. The finite element models are illustrated in Figures 1, 4 and 7 of Appendix B.

The maximum stress and temperature values obtained on the three types of spacers are given in Table 3-1 below.

Table 3-1

| Point |  | Type A | Type B | Type C |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{~S}(\mathrm{MPa})$ | 353 | 370 | 382 |
|  | $\mathrm{~T}\left({ }^{\circ} \mathrm{C}\right)$ | 550 | 550 | 550 |
| 2 | $\mathrm{~S}(\mathrm{MPa})$ | 290 | 240 | 250 |
|  | $\mathrm{~T}\left({ }^{\circ} \mathrm{C}\right)$ | 620 | 750 | 750 |
| 3 | $\mathrm{~S}(\mathrm{MPa})$ | 200 | 100 | 170 |
|  | $\mathrm{~T}\left({ }^{\circ} \mathrm{C}\right)$ | 820 | 820 | 820 |

Figures 2, 5 and 8 of Appendix $B$ show the temperature distribution in each one of the three spacer configurations. Figures 3, 6 and 9 show the stress distribution in each one of the three spacer configurations.

Analyses of other geometrical configurations have been carried out and the following results obtained:

- Double-A configuration (Figure 10, Appendix B) 玉 The resulting stress state is similar to that obtained with the Type A configuration
a Double-C configuration (Figure 11, Appendix B) ㄹ The resulting stress state is similar to that obtained with the Type $C$ configuration
a Configuration Type B, with curved ends (Figure 12, Appendix B) E The stress state obtained in this configuration is more critical than that in configuration Type B

The following conclusions can be derived from the stress analyses carried out for normal operating conditions:

- Considering a maximum allowable secondary stress limit of $2 \times R p_{02}$, the stress states obtained at different temperatures are higher than these maximum value
- This means that the material will suffer slight permanent/plastic deformations which will accumulate with the hot duct thermal cycles
- The maximum allowable number of thermal cycles subject to fatigue for this stress level can be estimated as $n>10^{5}$ cycles, in accordance with ASME III Division 1-NH (Figure T-1420-1B)
a Since the allowable number of thermal cycles subjected to fatigue $n>10^{5}$ is far greater than the foreseen startup and shutdown number of cycles during the plant lifetime, it is considered that no cracks will appear in the different metal parts of the hot duct due to material fatigue

### 4.2.2 Stress States during Thermal Transients

Stress analyses have been carried out for the most unfavourable thermal transient load case, indicated in section 3.3.2. The following have been considered in these transient analyses:

- Variation in the external He temperature of $\boldsymbol{\Delta T}=-23^{\circ} \mathrm{C} / \mathrm{s}$ (hot side) for $\approx 9 \mathrm{~s}$. At the end of the transient, the He temperatures considered are $\approx 650^{\circ} \mathrm{C}$ on the hot side and $\approx 375^{\circ} \mathrm{C}$ on the cold side
a It has been considered that the He flow is maintained during the thermal transient, imposing He-wall heat exchange coefficients of $\approx 1500 \mathrm{~W} / \mathrm{m}^{2} \mathrm{~K}$ in the hot duct and $\approx 1300 \mathrm{~W} / \mathrm{m}^{2} \mathrm{~K}$ in the cold duct
- A thermal transient of 310 s was analysed so that after the first 9 s the external He temperature is kept constant, both on the hot side and the cold side

The analyses of the thermal transients for the different hot duct configurations $\mathrm{A}, \mathrm{B}$ and $C$ produced similar results:
. During the $\approx 9 \mathrm{~s}$ thermal transient, the following wall temperature variation values were produced: liner $850^{\circ} \mathrm{C} \equiv \approx 845^{\circ} \mathrm{C}$; support tube $488^{\circ} \mathrm{C} \equiv \approx=460^{\circ} \mathrm{C}$

- A period of time in excess of 300 s is required to raise the temperature of the pipe walls to a temperature close to that of the external He
a The maximum stress states on the metal connecting part are obtained approximately 200 s after the transient begins. The maximum stress states reached in the cold part of the connecting spacers increase by approximately $75-80 \%$ with respect to the stresses in normal operating conditions. The maximum stresses on the hot part of the connecting spacers are maintained approximately the same as the values obtained for normal operating conditions

The maximum stress states reached during thermal transients for the three types of spacers is $\mathrm{S} \approx 650 \mathrm{MPa}$ at a maximum temperature of about $550^{\circ} \mathrm{C}$.

This thermal stress state is more critical than that obtained during normal operating conditions. Therefore the accumulated deformation in the metal spacer would increase with these types of events.

Taking into account that the connecting spacer is axisymmetrical, the deformation and the thermal loads are also axisymmetrical. The deformation will practically have no effect on either the liner or the support tube because the stress states on these components are lower than the maximum values obtained.

The maximum allowable number of thermal cycles subject to fatigue for these levels of maximum stresses and temperatures obtained in the thermal transients can be estimated as $\mathrm{n}>500.1000$ cycles, in accordance with ASME III Division 1-NH (Figure T-1420-1B).

If the number of cycles ( n ) is exceeded, small fissures may appear in the metal connecting part. This will not cause any significant problems, as long as the cracks are not big enough to considerably diminish the stiffness provided by the metal connecting spacer.

### 4.3 STRUCTURAL STIFFNESS OF THE SPACERS

The stiffness of each of the different types of connecting spacers have been analysed.

The stiffness is calculated under the following conditions:

D The radial displacement of the external face of the support tube is restricted
a To obtain the radial stiffness, a unit radial displacement is introduced into the liner and the axial displacement is restricted. The radial reaction between the liner and the metal spacer is obtained

- To obtain the axial stiffness, a unit axial displacement is introduced into the liner and the radial displacement is restricted. The axial reaction between the liner and the metal spacer is obtained

The following are the stiffness results obtained for the three types of connecting spacer analysed:

| Stiffness | Type A | Type B | Type C |
| :--- | :---: | :---: | :---: |
| Radial $(\mathrm{N} / \mathrm{m})$ | $2.8 \mathrm{E}+9$ | $7.3 \mathrm{E}+9$ | $8.1 \mathrm{E}+9$ |
| Axial $(\mathrm{N} / \mathrm{m})$ | $3.0 \mathrm{E}+9$ | $5.0 \mathrm{E}+9$ | $2.5 \mathrm{E}+9$ |

If we take the axial stiffness of the duct as the most representative stiffness, we can see that a Type B connection is practically equivalent to the double-A or double-C type connections.

### 4.4 HEAT TRANSFERRED THROUGH THE INSULATION

An analysis has been carried out of the heat transmitted through the insulating wall (thermal losses) between the liner and the external support tube, based on the following calculation conditions:

- Temperature of the external face of the support tube $\Rightarrow 488^{\circ} \mathrm{C}$
- Temperature of the internal face of the liner $\underset{\boldsymbol{D} 850^{\circ} \mathrm{C}}{ }$

U Thermal conductivity of the insulation $\mathrm{K}=0.55 \mathrm{~W} / \mathrm{mK}$

- Conductivity of the metal parts 三see section 3.2

The analysis of the heat transferred has been carried out for a meter length hot gas duct, with the metal spacer centred in that portion of the duct. The results of the heat transferred for each of the different types of spacers are provided in the following table:

| Type A | Type B | Type C | Type Double A | Type Double C |
| :---: | :---: | :---: | :---: | :---: |
| $10.3 \mathrm{~kW} / \mathrm{m}$ | $12.0 \mathrm{~kW} / \mathrm{m}$ | $11.8 \mathrm{~kW} / \mathrm{m}$ | $11.0 \mathrm{~kW} / \mathrm{m}$ | - |

It can be seen that Type B spacers transmit 16\% more heat than Type A spacers and $10 \%$ more than double-A type spacers.

### 4.5 CONCLUSIONS FOR THE DESIGN OF THE SPACERS

The following conclusions can be derived from the analyses of the different types of metal connection spacers between the support tube and the liner:

0 From the manufacturing point of view, the Type A connection requires machining of the metal connecting parts. On the other hand, connection Types B and C would be formed by cut plates welded together and in turn welded to the support tube and the liner
a From the point of view of maximum thermal stresses, the three types of connections give similar stress results

D For spacer Types B and C, the stress states on the connections with the support tube and the liner are low, which means it would be acceptable to weld them together
a From the point of view of stiffness, the Type B connection is the stiffest, being equivalent to a double-A or double-C type connection

- From the point of view of heat transferred through the insulating wall (thermal losses), the Type A connection gives better thermal insulation compared to the other types of connections

## 5. FIBRE FILTERING DURING PRESSURE DROP

### 5.1 GEOMETRICAL CONFIGURATIONS OF FILTERS STUDIED

Sudden external He pressure drop events can give rise to the entrainment of insulation fibres from the thermal insulation chamber into the hot duct. To prevent this, a filter system shall be installed which guarantees that:
a The thermal dilations between the external support tube and the liner are compatible, so that the stresses on the connecting part are as low as possible

D Insulation fibres are prevented from getting inside the hot duct

Two types of filters have been studied and are defined in Figures D and E of Appendix A. The geometrical manufacturing characteristics of each of the filters are described below.

### 5.1.1 Type A Filter $=($ Reference Design, Ref 2), Figure D, Appendix A

U The thermal insulation is separated from the liner by a 5 mm thick, perforated internal pipe which is welded to a machined part installed in the liner
a Axial thermal deformation is made compatible by allowing the axial dilation of the 5 mm pipe in a contact area between the two pipe sections (see Figure D, Appendix A). Given the high temperatures $\left(850^{\circ} \mathrm{C}\right)$ of this contact area, it requires very precise machining and surface treatment
a To prevent the entry of fibres in the helium flow, a closed chamber is created between the liner and the 5 mm perforated pipe. This chamber is sealed by machined ceramic rings which are connected to the 5 mm pipe and are in contact with the liner pipe

- The chamber is approximately 20 mm thick and reduces the space occupied by the thermal insulation. A comparison of filter Type A with filter Type B shows that filter Type A will transfer approximately 20\% more heat through the hot duct than filter Type B

### 5.1.2 Type B Filter - Ring-type Filter, Figure E, Appendix A

a The filter is manufactured in the form of a ring, as a part independent of the hot duct. This filter comprises the following parts:

- $\quad 5 \mathrm{~mm}$ perforated internal and external pipes
- 2 lateral, cut plates on which the perforated pipes are mounted and welded. The filter is installed between the two 5 mm perforated pipes
- Filter formed by wrapped fibre insulation arranged circumferentially and compacted. The filter fibre is separated from the 5 mm perforated pipes by means of metal wire mesh
a The ring-type filter is installed in the hot duct by means of two lateral L-shaped profiles welded to the liner. The joint is made using a flexible temperatureresistant material and screws with axially elongated holes for thermal dilation. Once the screws have been inserted they can be spot welded

### 5.2 PRESSURE DROP IN THE INSULATING CHAMBER

### 5.2.1 Type A Filter (Reference Design, Ref. 2)

During He pressure drop events with this type of filter, the maximum pressure drop between the He of the internal thermal insulation chamber and the external He is produced in the gap section located in the contact between the ceramic rings and the liner. The pressure drop in the thermal insulation is considered negligible (see pressure drop with Type B filter).

A finite model was built of a hot duct section with a Type A filter (see Figure 13, Appendix B). Analyses were carried out with this model and the following results obtained:

- If it is assumed that the ceramic rings make contact with the liner before the hot duct is heated to operating temperatures, when these temperatures are reached the liner is displaced in radial direction to a value 5 mm more than that of the ceramic rings due to the different thermal expansion coefficients. Both parts will continue to be in contact and there will be a radial compression force of $\mathrm{Fr}=8 \mathrm{E}+5 \mathrm{~N} / \mathrm{m}$ between each of the ceramic rings and the liner
a A higher pressure inside the thermal insulation chamber with respect to the cold gas side He (between 1 and 7 MPa ) will not cause any significant relative opening between the rings and the liner, especially the outer ceramic ring, which is the ring that retains the pressure

Therefore, assuming contact between the rings and the liner, the cold gas side He pressure drop events will not cause any opening between the ceramic rings and the
liner. The thermal insulation chamber could therefore become overpressurised and give rise to unallowable stress states.

Therefore, in order to control the pressure drop process in the insulating chamber, it must be ensured that there is a discharge opening between the ceramic rings and the liner during hot duct operating conditions and during the different thermal transients.

This required discharge opening will have to be calculated to obtain the desired differential pressure in the insulating chamber with respect to outside pressure, so as to produce acceptable stress states.

### 5.2.2 Type B Filter

To calculate the pressure drop inside the thermal insulation during He pressure drop events in accordance with section 3.4, the following values were used:
$\therefore \quad$ Variation in maximum pressure $\equiv \mathrm{CP}=1.0 \mathrm{MPa} / \mathrm{s}$

- Volume of He enclosed between the two spacers $\equiv \mathrm{Vo} \cong 0.7 \mathrm{~m}^{3}$, considering a distance of $\curvearrowleft 1.6 \mathrm{~m}$ between spacers
a. Minimum He flow area $\equiv$ As $\cong 0.2 \mathrm{~m}^{2}$, section between the filter and the wall of the support tube. A length of $\mathrm{Lp} \approx 0.2 \mathrm{~m}$ is conservatively considered as maximum length with a minimum flow area section (As)

If we assume that the pressure drop GP occurs from normal operating conditions E $\mathrm{P}_{1}=7.2 \mathrm{MPa} ; \mathrm{T}_{1}=850^{\circ} \mathrm{C} ; \mathrm{d}_{1}=3 \mathrm{~kg} / \mathrm{m}^{3}$, in accordance with section 3.5 the maximum velocity reached by the He in the section As will be $\mathrm{V}_{2}=0.3 \mathrm{~m} / \mathrm{s}$. In accordance with section 3.4 the pressure drop value in the section As for an insulation material length Lp can be estimated as:

$$
\boldsymbol{\Delta P} \approx 4 \times \operatorname{Lp} \times \mathrm{d}_{1} \times 680 \times \mathrm{V}_{2}^{1.097}=0.435 \mathrm{E}-3 \mathrm{MPa}
$$

If we assume that the pressure drop GP occurs in low pressure operating conditions $\Rightarrow \mathrm{P}_{1}=2.0 \mathrm{MPa} ; \mathrm{T}_{1}=500^{\circ} \mathrm{C} ; \mathrm{d}_{1}=1.2 \mathrm{~kg} / \mathrm{m}^{3}$, in accordance with section 3.5 the maximum velocity reached by the He in the section As is $\mathrm{V}_{2}=1.0 \mathrm{~m} / \mathrm{s}$. In accordance with section 3.4 the pressure drop value in the section As for an insulation material length $L p$ can be estimated as:

$$
\boldsymbol{\Delta P} \approx 4 \times \operatorname{Lp} \times \mathrm{d}_{1} \times 680 \times \mathrm{V}_{2}^{1.097}=0.787 \mathrm{E}-3 \mathrm{MPa}
$$

A similar pressure drop value would be obtained in the fabric insulation (see section 3.4).

As may be seen, the pressure drop value in the insulation can be considered insignificant compared to the value GP . It can therefore be ensured that the pressure inside the insulating chamber will be practically the same as the pressure of the cold side gas He during pressure drop events.

### 5.3 STRESSES ON THE FILTER STRUCTURE

### 5.3.1 Type A Filter (Ref. 2)

If the joint between the ceramic rings and the 5 mm perforated pipe which supports them is rigid, very high stress states will occur in the ceramic rings due to the different thermal expansion coefficients between the steel and the ceramic material.

The ceramic rings should therefore be connected to the 5 mm pipe in such a way that the joint is not rigid, allowing a different radial displacement between the two components. It would be recommendable that the rings were not continuous, but rather that they were assembled in segments so that dilation of the ceramic material would not produce circumferential stresses.

### 5.3.2 Type B Filter

The filter is manufactured in the form of a ring, as a part independent of the hot duct.

The fibre fabric which serves as a filter is enclosed within the structure of two metal perforated pipes, which ensures that the filter wrapped fibre will not suffer relative axial displacements due to axial dilation of the hot duct.

The external metal perforated pipe of the filter will reach a temperature different to that of the internal perforated pipe which will generate a stress state between the two pipes. These thermal stress values can be very conservatively estimated as follows:

$$
\mathbf{a}=\frac{850-488}{2} \times \mathrm{E} \times \operatorname{cox} \times \frac{1}{2} \simeq 275 \mathrm{MPa}
$$

This secondary stress state could cause the material to suffer slight deformations which will accumulate during the startup and shutdown cycles, but they are far from the stress states that can cause cracks due to material fatigue.

The ring-type filter is installed in the hot duct by means of two lateral L-shaped profiles welded to the liner. The joint is made using a flexible temperature-resistant material and screws with axially elongated holes for thermal dilation.

The use of flexible joints between the filter and the connecting part to the liner allows different radial displacements of the liner and the filter structure so that stress states are not generated due to these relative displacements. In addition, these joints must prevent the entrainment of insulation fibres through the joints during He pressure drop events.

## 6. CONCLUSIONS

Based on the hot gas duct reference design (Ref. 2), thermomechanical calculations have been carried out for the both the normal operating conditions and transients. In particular, the design of the connecting spacers and the behaviour of the thermal insulation was analysed.

Connecting spacers:

Three types of connecting spacers have been analysed (A, B and C), which are defined in Figures A, B and C of Appendix A. Type A being the reference design (Ref. 2).

From the point of view of manufacturing and assembly, spacer Types B and C do not require any kind of special machining and can be welded directly to the support tube and the liner.

From the point of view of mechanical stiffness, spacer Type B is the most rigid with a stiffness comparable to a double-A type spacer or a double-C type spacer.

The maximum stress state on the spacers is reached during the thermal transient event analysed, which gave stress states of the order of $75-80 \%$ greater than those in normal operating conditions. This maximum stress state is reached approximately 200 s after initiation of the event.

The maximum stress states can reach values which give rise to cracks in the spacer due to metal fatigue, based on a number of thermal transient cycles of the order of $\mathrm{n} \cong 500 \quad 1000$ cycles.

Regarding the heat transferred through the insulation, Type A has better thermal insulation with $10.3 \mathrm{Kw} / \mathrm{m}$ of thermal losses.

Fibre filtering:

Two types of filters (A and $B$ ) have been studied, as defined in Figures $D$ and $E$ of Appendix A, filter type A being the reference design.

From the point of view of manufacturing and assembly, filter Type B is made as an independent part which is mounted on the liner structure and joined to it by sealed, flexible joints and screwed to parts with elongated holes so that the joint is not subjected to thermally induced forces.

During external He pressure drop events, with the Type $B$ filter there will be no significant differential pressure between the insulating chamber and the external He . With the Type A filter, the differential pressure in the insulating chamber could be significant and it would be necessary to control this pressure drop by ensuring some depressurisation openings.

Work-Report NGPM5/2003/en/0285 from 30.12.2003, FANP GmbH

FRAMATOME ANP

The present design for the Hot Gas Duct, especially the distance pieces between the inner liner and the support tube, is evaluated for the operational conditions and one Accident Load Case. For the incident and accident conditions conclusions are made.

The evaluation based on the preliminary KTA 3221.1 and KTA 3221.2. The Hot-Gas-Duct with operating conditions of $488^{\circ} \mathrm{C}$ at the support tube und $850^{\circ} \mathrm{C}$ at the inner liner is classified for Temperature category III. With respect to the classification include the structural analysis evaluation of primary and secondary strains and stresses and the consideration of elastic-plastic material behaviour together with the assessment of creep behaviour. The threshold values are time-temperature depending values.

The evaluation is done by the FE-Method with the computer code ANSYS 7.1.
With respect to the available information and made estimations we can conclude that the design resist the load for the normal operation (usage factor 0,11 ). Critical items are stress concentration with respect to material and geometrical discontinuities. Welds has to be minimized in principle and not considered here.

## 1 Introduction

The report describe the investigation of the present design for the Hot-Gas-Duct for the High-Temperature-Reactor. The duct is part of the reactor power conversion unit and connect the reactor with the helium turbine. The duct has the purpose to conduct the high temperature helium from the reactor to the helium turbine (inside) and to feed the reactor with helium coming from the recuperator (outside).

To ensure the functionality a coaxial duct is designed. The support tube is protected with a thermal sleeve (liner) at the inner side. The liner is connected to the support tube via Vee-shape pieces. The Vee-shape has to be designed for thermal and mechanical loads coming from the different helium temperatures at both sides of the duct. Investigated are normal operating conditions and accident conditions. The normal operating conditions investigated with two different models. The first model is designed with two different materials. The chosen material for the support tube is the standard austenitic material 1.4571 . The Vee-shape and the liner are designed with the Alloy 800 H . The second model is using for all parts Alloy 800 H .

## 2 Design Data

### 2.1 Geometry

The geometrical dimension is taken from Ref. [1] to [3] (Appendices 1 to 3) and Ref. [10].

### 2.2 Material Data Base

Considered materials are taken from Ref. [1] to [3]. Material properties are taken from Ref. [4] and Ref. [5]. The temperature depending material properties are shown in the following graphs.

Figure 2-1: Multi linear Isotropic Hardening for 1.4571

Figure 2-8: E-Module Alloy 800H

Figure 2-10: Thermal Transfer Coefficient Alloy 800H

With respect to the high temperature and the classification is the creep behaviour to consider. This effect is implemented for the secondary creep behaviour by using the implicit creep equation in accordance to Norton described as follow:
acc. to Norton:

ANSYS creep model: $\quad \mathrm{s}_{\mathrm{cr}}=\mathrm{C}_{1 \times 2} \mathrm{Ce}^{\mathrm{C}} \mathrm{e}^{-\mathrm{C} 3 / \mathrm{T}}$
The coefficients are taken from Ref. [4] where the temperature depending values are published.

### 2.3 Loadings

The specified loads for pressure and temperature are described in Ref. [6] and Ref. [11]. Other external loads e.g. from seismic or pipe loads from supports or components are not considered.

### 2.3.1 Normal Operation Conditions

The investigated loads for normal operation consider for the primary stresses pressure differences of $0,8 \mathrm{MPa}$ and $0,2 \mathrm{MPa}$ for the liner and the vee-shape and1,5 MPa for the support tube. Load cycles are considered from Ref. [11] "Tabel 1: Functional specifications" with 1100 cycles in 6 years and a temperature variation of $+/-240^{\circ} \mathrm{C} / \mathrm{h}$.

### 2.3.2 Accident Condition

Considered are the loads from Ref. [6] "Table 1: functional specification" and herein the Accident conditions for the Primary Coolant Leak ( $\mathrm{DN}<250$ ). The specified transient is the maximal load with respect to the maximal range of pressure and temperature and the strong gradients.

## 3 Structural Analysis

### 3.1 Principles of used Methodology

The evaluation will be based on the methodology described in Ref. [4]. If the component have to be designed for transient load conditions together with time dependant material properties, is during the dimensioning not only the dimensioning level with the analysis of the primary stresses to evaluate, then the secondary stresses under consideration of the different operational levels and the fatigue aspect have to be analysed (see Ref.[4] Chapter 4.3.2).

Depending on the mechanical behaviour and with respect to Temperature-Time-Limitcurves different classifications are defined. The Hot-Gas-Duct is in the class of high temperature with significant creep behaviour.

Primary stresses related to the outer loads and can be separated in ordinary membrane stress Pm, local membrane stress PI or local bending stress Q. Within the evaluation of the Hot-Gas-Duct is the relevant load for the primary stresses the inner pressure and will be analysed in Chapter 3.4.1.

Secondary stresses e.g. related to unsteady geometry and or because of different temperature distributions be separated in membrane stress $Q$ and bending stress $Q$ for the component geometry we have to consider herein. The secondary stresses analysed in Chapter 3.4.2 (time history of

Handling: restriktiv
temperature distribution) and 3.4.3. The assessment of secondary stresses have to be seen in the scope of the fatigue evaluation.

The evaluation of fatigue with relevant creep behaviour based on the assessment of strains and will be analysed in Chapter 3.4.4.

Handling: restriktiv

### 3.2 Structural FE-Model

The structural model is considering the geometry, material properties and loads are described in Chapter 2. The chosen model is a two dimensional axial symmetric model. At both ends of the model the boundary conditions defined in a way, that the radial displacements are taken the ongoing duct in to account. It is also valid for the axial displacements. The "hole-plate" is modelled for free axial strain. Furthermore is the mesh generated to guarantee adequate results for high thermal transient load and for the geometric nonlinearities. The elements are plane and axisymmetric defined by 4 nodes by having 2 degrees of freedom per node. The model and the boundary conditions are shown in the following picture.

Figure 3-1: Element Mesh

Figure 3-2: Boundary Conditions

Handling: restriktiv

### 3.3 FE-Solution Method

The implicit Finite-Element-Method is used to get adequate results with respect to the transient analysis under consideration of geometry and material nonlinearities e.g. plastic strain and creep.

For the analysis of normal operating conditions is the temperature distribution calculated by a transient analysis with 124 time steps and 305 cumulative iterations. The following quasi static structural analysis takes into account 48 time steps with 288 cumulative iterations. The adequate chosen time steps considering the time period where changes in temperature or pressure happened. In particular temperature differences over the wall thickness are considered to evaluate effects for membrane and bending strain and stress. The same procedure is used for the analysis of the accident conditions.

### 3.4 Results

### 3.4.1 Primary Stress (Membrane stress related to inner pressure)

The primary stress for the pressure load is calculated for cylindrical parts with shell characteristic:

| $\sigma_{u} \in \mathrm{pi} \frac{\mathrm{di}}{2 \cdot \mathrm{~s}}$ | Circumferential stress |
| :---: | :---: |
| $\sigma_{\mathrm{r}} \equiv \frac{-\mathrm{p} i}{2}$ | Radial stress |
| $\sigma_{1} \equiv \frac{\Phi_{u}}{2}$ | Logitudenal stress |
| $s_{\mathrm{v}} \mathrm{Em} \mathrm{s}_{\mathrm{u}} \mathrm{s}_{\mathrm{r}}$ | Equivalent stress acc. to Tresca (max-min) |

The results for the primary stress at the liner, the vee-shape und the support tube are shown in Table 3-1.

| Part / $\bar{\sigma}_{v}$ [MPa] | liner | vee-shape | support tube |
| :---: | :---: | :---: | :---: |
| $\mathrm{p}=0,2 \mathrm{MPa}^{* 1}$ | 1,46 | 3,635 | 0,67 |
| $\mathrm{p}=0,8 \mathrm{MPa}^{* 1}$ | 5,84 | 14,54 | 2,68 |
| $\mathrm{p}=1,5 \mathrm{MPa}^{* 1}$ | - | - | 5,025 |
| $\mathrm{p}=4,5 \mathrm{MPa}^{*}{ }^{2}$ | - | - | 15,075 |

| Dimensions <br> [mm] | liner | vee- <br> shape | support <br> tube |
| :---: | :---: | :---: | :---: |
| Inner <br> diameter | 1450 | 1450 | 1650 |
| Wall thick- <br> ness [s] | 10 | 4 | 25 |

Table 3-2: Geometrical Parameter

Handling: restriktiv

### 3.4.2 Time History of Temperature Distribution

Adiabatic conditions are considered. The insulating material is implemented with a thermal conductivity of $0,426 \mathrm{~W} / \mathrm{mK}$ in acc. to Ref. [7]. The heat transfer coefficient at the outside of the support tube is chosen $1300 \mathrm{~W} / \mathrm{m}^{2} \mathrm{~K}$ and $1500 \mathrm{~W} / \mathrm{m}^{2} \mathrm{~K}$ for the inner side. The solution for temperature distribution at several time steps is shown in the following figures. The distribution is showing the expected linear distribution from the outside of the support tube to the inner side of the liner. The figures will show the temperature distribution for three several time steps.

Figure 3-3: Temperature Distribution at 662337 sec (Normal Operation)
Cold shock at the outside of the support tube with $60 \mathrm{~K} / \mathrm{sec}$.

|  |  | 665956 | 829,6 | 10,5 | 32,32 |
|  |  | 1,4E+7 | 30 | 63,2 | 393,7 |
|  | 164 / 168 | 12300 | 628,4 | 20,2 | 136,1 |
|  |  | 665956 | 622,9 | 30,1 | 123,6 |
|  |  | 1,4E+7 | 30 | 220,1 | 292,9 |
| All Parts Alloy 800H (Accident Conditions) | 310 / 314 | 3000 | 522,9 | 136,6 | 284,0 |
|  |  | 10003 | 530,4 | 158,2 | 318,3 |
|  |  | 16011 | 717 | 4,6 | 31,5 |
|  | 164 / 168 | 3000 | 654,1 | 89,3 | 157,4 |
|  |  | 10003 | 709,5 | 101,2 | 164,3 |
|  |  | 16011 | 780,9 | 12,0 | 37,1 |

Table 3-3: Linearized Secondary Stress (membrane and bending)

The values are taken from the listed output in Appendices 6 to 8 .
The following figure is showing the equivalent stress in acc. to v.Mises at the model with different materials during normal operation time at 56579 sec . The maximum value is near the location where the material changed and in the area of heat affection zone of the weld.

This model will not be further investigated for the evaluation of strains and the fatigue. More remarks made under Conclusions in Chapter 4.2.

Handling: restriktiv

Figure 3-8: Equivalent Stress during Normal Operation for the Model with Different Materia

### 3.4.4 Fatigue Evaluation (elastic, plastic, thermal and creep strains)

The results for strains are shown as time histories for the elastic, plastic, thermal and creep strains for the nodes equivalent to the stress evaluation. The figures are related to the model with single material Alloy 800 H and the load case Normal Operation. The equivalent strains are not linearized and the smaller share of membrane and membrane+bending strains is not shown. The maximum equivalent strain including peak share of $0,8 \%$ in Figure 3-10 is shown.

## 4 Assessment

The analysis for the hot gas duct has with the temperature of $\sim 850^{\circ} \mathrm{C}$ significant creep behaviour. To consider the creep effect are different aspects to investigate. The analysis required elasticplastic material behaviour for the adequate determination of strains and stresses. The threshold values are time, temperature and depending on the number of load cycles. The separate analysis should show the influence of creep for the strain accumulation.

### 4.1 Comparison of Evaluation Criteria and Analytical Results

For the pressure related membrane stress are threshold values $(\mathrm{St})$ depending of the material, operating time and temperature given as follow from Ref. [4] for Alloy 800H:

| Oper. Tem- <br> perature | Operating <br> time [h] | St <br> [MPa] |
| :---: | :---: | :---: |
| 850 | $10^{5}$ | 8 |
| 775 | $10^{5}$ | 17 |
| 700 | $10^{5}$ | 30 |

Table 4-1: Evaluation Criteria Membrane Stress

The maximum membrane stress is $\sim 15 \mathrm{MPa}$ (Table 3-1) for Normal Operation. To consider linear interpolation for the location of the vee-shape, with temperature of not more then $775^{\circ} \mathrm{C}$, is the criteria for the membrane stress fulfilled. For $850^{\circ} \mathrm{C}$ and 100 h operating time is the St-value given with 35 MPa . For the accident conditions was the primary membrane stress $15,075 \mathrm{MPa}$.

Handling: restriktiv

| Q |  |  |
| :---: | :---: | :---: |
| Temperature <br> $\left[{ }^{\circ} \mathrm{C}\right]$ | $\mathrm{S}_{\mathrm{m}}$ <br> $[\mathrm{MPa}]$ | $3 \mathrm{~S}_{m}$ <br> $[\mathrm{MPa}]$ |
| $20-250$ | 115 | 345 |
| 500 | 101 | 303 |
| 650 | 95 | 285 |
| 700 | 91 | 273 |
| 750 | 88 | 264 |
| 800 | 83 | 252 |
| 850 | 72 | 216 |

Stresses in MPa, the given values valid for Alloay 800 H . The criteria is for the dimensioning the same for membrane or membrane +bending.

Table 4-2: Evaluation Criteria in acc. to Ref. [4]

The $3 S_{m}$ criteria is not for all stresses given in Table 3-3 fulfilled. The following strain evaluation has to be done if the 3 Sm criteria is exceeded. With respect to the temperature classification is the strain evaluation with limited plastic and creep strains necessary anyway.

Following limitations for equivalent strains in principal are required for all Load Classes without Accident Cases:

- membrane strain to $\leq 1 \%$
- membrane+bending strain to $\leq 2 \%$
- local membrane+bending strain to $\leq 5 \%$

For the load case Normal Operation is a maximal membrane strain of $0,45 \%$ at the path node 1840-1792 (Appendix 9, page 28) evaluated. The membrane + bending strain is $1,66 \%$ at the same path (Appendix 9, page 28). The limits above are fulfilled.
For the Accident conditions is a maximal total equivalent strain of 13,8 \% evaluated (Appendix 10, page 29). It has to be considered that the linearized strains total strain and contain elastic, plastic and creep strains. It is not to understand as strain range.

For the thermal fatigue evaluation is the separated evaluation for the influence of creep strain $\left(D_{c r}\right)$ and plastic strain $\left(D_{\text {pl }}\right)$ required. The relevant criteria in acc. to Ref. [4] for the plastic strain:

$$
\begin{array}{cr}
n_{i} & - \text { amount of cycles per load case } \\
\begin{array}{c}
n_{i a l l o w a b l e ~} \\
\text { cycle }_{i} \text { at }
\end{array} & \text { - allowable number of cycles for } \Delta s_{i} \text { at load } \\
& \text { temperature } t_{i}
\end{array}
$$

$n_{\text {iallowable (Normal Operation) }} \sim 10^{4}\left(\right.$ at $850^{\circ} \mathrm{C}$ and $\boldsymbol{\Delta} \boldsymbol{z} / 2=0,427 \% / 2 \sim 0,2 \%$ taken from Appendix 11 ); $\mathrm{n}_{\mathrm{i}}=1100$
$\mathrm{n}_{\text {iallowable (Accident Conditionsn) }} \sim 5\left(\right.$ at $700^{\circ} \mathrm{C}$ and $\boldsymbol{\Sigma} / \mathrm{s} / 2=9,7 \% / 2 \sim 4,9 \%$ taken from Appendix 12 ); $\mathrm{n}_{\mathrm{i}}=2$

Handling: restriktiv
$\mathrm{D}_{\text {pl Normal Operation }}+\mathrm{D}_{\text {pl Accident Conditions }} \leq 1$
The usage factor for the normal operation is $\mathrm{D}=0,11$. For the accident conditions are app. 5 load cycles allowable.

To consider the creep strain in acc. to Ref. [2]:

\titi - time per cycle
$\mathrm{t}_{\mathrm{oall}}$ - allowable load time based on $1,1 \mathrm{St}$ see Table 4-1
For normal operation are 1100 cycles in 6 years specified. It would be 46 hour per cycle, which is not realistic. More realistic are 12 cycles in 6 years with a time per cycle of 4000 h . The used Input values are:

| Load case | $\boldsymbol{\Delta t i}$ | $\mathrm{t}_{0 . a l}$ | $\mathrm{n}_{\mathrm{i}}$ | $\mathrm{n}_{\text {iallowable }}$ |
| :--- | :--- | :--- | :--- | :--- |
| Normal operation: | 4000 | 100.000 | 12 | 10.000 |
| Accident Condition: | 2 | 100 | 2 | 5 |

Plastic Strain: $\quad D_{p \mid}=D_{\text {pl Normal Operation }}+D_{\text {pl Accident Condition }}=0,0012+0,4=0,4012$
Creep Strain: $\quad D_{c r}=D_{\text {cr Normal Operation }}+D_{\text {cr Accident Condition }}=0,48+0,04=0,52$
$D_{\text {total }}=0,92$

### 4.2 Conclusions

The investigated design for the hot gas duct seems to resist the defined loadings. To take care of the estimations and that not all load case considered, material discontinuities should be neglected. Furthermore it should be considered that welds have to be minimized and the geometrical design should preclude any stress concentration. A final statement and design optimization should include further load cases and the check if any further loads from boundary conditions has to be considered (e.g. pipe- or seismic loads).
